state. They will be tested again after having been age-regressed during hypnosis to their premorbid state, and finally after having been given a posthypnotic suggestion of having regained health. If hypnosis can remove anxiety in the face of actual brain damage, these truly brain-damaged subjects should perform better under such hypnotic and posthypnotic conditions.

Hypnosis as a neurocognitive rehabilitation tool

Given the extensive and growing knowledge of the cognitive architecture for many neuropsychological and neuropsychiatric disorders and the ability of hypnotic suggestion to reliably modulate performance at cognitive, behavioural and experiential levels, an underexploited opportunity remains for using hypnosis to make a meaningful contribution to neuropsychological interventions in the

Scientific papers on hypnosis and brain injury

⌚ 30. May 2017

This is an attempt to make a complete up-to-date list of all literature pertaining to hypnosis and brain injury. I now consider the literature so big and dispersed that I feel quite confident that my list won't be complete, but hopefully, it can get close. In each section, the most informative paper(s) are highlighted in green font.

This list contains many case-studies so there is likely a strong positive bias. I would advise reading the

Cognition

Status (April 2018): Completed.

Summary of the literature: There are [large] positive effects of hypnosis on cognition following acquired brain injury.

- Cui-ping, L. L. (2011). Influence of hypnosis therapy on recovery of hemorrhagic stroke. *Journal of Tashan Medical College*, 20(1), 025. http://en.cnki.com.cn/Article_en/TJUDT01AL-T5YK201101025.htm (see my English translation and comments)
- deo, R., showing large effects ($SMD = 0.16 \pm 0.21$) on Sonthof, anxiety, and depression in stroke patients given ten sessions of hypnosis between one and twelve weeks after the infarct onset. The study is relatively large with 120 treatment-as-usual patients of which 40 had additional adaptive hypnosis. It was published in Chinese in a Chinese journal with impact factor 0.5, and it's unclear whether it was peer-reviewed. In general, there are many reasons to be skeptical of the quality of this paper. Nonetheless, everything else being equal, it does increase the probability that hypnosis can improve cognition following acquired brain injury. With the help of Chinese friends, I got hold of the paper and found reading it. I added a link to the translation in the reference above, containing comments to clearly particularize sections and discuss statistics.
- Lindleis, J. K., Overgaard, R., & Overgaard, M. (2017). Improving working memory performance in brain-injured patients using hypnotic suggestion. *Brain*, 140(4), 1100–1106. <https://doi.org/10.1093/brain/aww301>.
Our study, showing a large specific effect on working memory performance of hypnotic suggestions inducing the return to preoperative memory function. It's an RCT with a total of 16 patients stratified to targeted hypnosis, an active control, and a passive control. The effect of four and eight treatment sessions is assessed with long-term follow-up.
- Milos, R. (1975). Hypnotic exploration of amnesia after cerebral injuries. *International Journal of Clinical and Experimental Hypnosis*, 23(2), 103–110. <https://doi.org/10.1080/00207747508415934>
In this paper, author reports on cognitive remediation but it does manage to (partially) get retrospective reports of experiences that were otherwise inaccessible due to retrograde or anterograde amnesia during hypnosis. 7 out of 20 cases of severe injury. It was not checked whether these reports were more accurate, so this is prone to confounders or changes in response of the interview rather than a true cancellation of amnesia.
- Sullivan, D. S., Johnson, A., & Bratkovitch, J. (1974). Reduction of behavioral deficit in organic brain damage by use of hypnosis. *Journal of Clinical Psychology*, 30(1), 96–98. <https://doi.org/10.1002/1607-4997.CP227030133-3.0.CO;2-4>
Later we discovered this similar study had been carried out by [Sullivan et al. \(1974\)](#). The Sullivan study, however, had an intervention consisting of just Seven sessions repeated twice – probably less than two minutes. They obtained a small positive effect on the Picture Completion task from the WAIS battery but not on the Bender-Gestalt test. They had a quite small sample, and the two-page article leaves many details unreported.
- Vanhaudenhuyse, A., Laureys, S., & Faymonville, M.-E. (2015). The use of hypnosis in severe brain injury rehabilitation: a case report. *Acta Neurologica Belgica*, 115(4), 771–772. <https://doi.org/10.1007/s13780-015-0459-3>
A brief report on a 55-year-old man with cerebral hemorrhage who underwent hypnosis when he was deemed chronic with severe symptoms. Hypnosis sparked further improvement. As a side note, the authors write that "To the best of our knowledge, this is the first study reporting on the integration of hypnosis as part of rehabilitation treatment of severe brain injury patients." Well. ☺

Motor disorders

Status (April 2018): Approximately 20% completed. Needs a search for post-2000 literature, references, and citations.

- With the notable exception of [Sparks & Freeman \(1962\)](#) and [Inman et al. \(2016\)](#), this literature consists largely of single-case studies, making it very vulnerable to publication bias. Confirming this, most studies report positive findings while [Sparks & Freeman \(1962\)](#) only report positive outcomes for four out of nineteen patients with cerebral palsy. Although somewhat disconcerting, this observation may not generalize to all of the literature given the large variability in the patient characteristics and treatment protocols between papers.
